NLP

Imagine you work for Google News and you want to group news articles by topic

Or you work for a legal firm and you need to sift through thousands of pages of legal documents to find relevant ones.

This is where NLP can help!

NLP

We will want to:

- Compile Documents
- Featurize Them
- Compare their features

NLP

Simple Example:

- You have 2 documents:
 - “Blue House”
 - “Red House”
- Featurize based on word count:
 - “Blue House” \rightarrow (red,blue,house) \rightarrow (0,1,1)
 - “Red House” \rightarrow (red,blue,house) \rightarrow (1,0,1)

NLP

- A document represented as a vector of word counts is called a “Bag of Words”
 - “Blue House” -> (red,blue,house) -> (0,1,1)
 - “Red House” -> (red,blue,house) -> (1,0,1)
- You can use cosine similarity on the vectors made to determine similarity:

$$\text{sim}(A, B) = \cos(\theta) = \frac{A \cdot B}{\|A\| \|B\|}$$

NLP

- We can improve on Bag of Words by adjusting word counts based on their frequency in corpus (the group of all the documents)
- We can use TF-IDF (Term Frequency - Inverse Document Frequency)

NLP

- Term Frequency - Importance of the term within that document
 - $TF(d,t)$ = Number of occurrences of term t in document d
- Inverse Document Frequency - Importance of the term in the corpus
 - $IDF(t) = \log(D/t)$ where
 - D = total number of documents
 - t = number of documents with the term

NLP

- Mathematically, TF-IDF is then expressed:

$$w_{x,y} = \text{tf}_{x,y} \times \log \left(\frac{N}{\text{df}_x} \right)$$

TF-IDF

Term x within document y

$\text{tf}_{x,y}$ = frequency of x in y

df_x = number of documents containing x

N = total number of documents
